The Strait of Hormuz stays closed

What happens to the world gas market over one year?

STRAIT CLOSED

1 QUESTION

Analyst	Waits about a month to see whether the closure lasts, then decides to start a study.

2 SCENARIO

Analyst	Describes the storyline: One year, strait open or closed, and Russian supply also cut.
Scenario agent	Proposes about 90 nodes instead of 136, with no seasons or storage. Blocks every LNG route out of the Gulf with very large distances, and asks about Gulf market power and pipeline expansion.
Analyst	Approves the node structure and the edits.
Code	Creates the variants. They differ only in the general workbook.

3 DATA

Data agent	Maps sources to the new nodes, drafts one year of projections, and proposes an elasticity class for each node.
Code	Aggregates pipeline capacities and recomputes shipping distances.
Data agent	Suggests the official domestic price as the Gulf reference price.
Analyst	Replies: That price is subsidised, far below what the model needs.
Data agent	Revises the value and proposes a lesson about subsidised prices.
Analyst	Approves the lesson. It is applied to the other countries with subsidised prices.

4 CALIBRATION On the baseline, with the strait open

Calibration agent	Diagnoses the deviations and proposes one change at a time.
Code and GGM	Apply the change, run the model and report the new deviations; the two repeat.
Analyst	Follows the log, corrects one diagnosis, and accepts the fit.

5 RUNS AND RESULTS

Code and GGM	Run every variant with the same calibration.
Results agent	Drafts where the missing LNG is replaced and which importers lose most, with the tables behind it, and flags odd patterns.
Analysts	Decide what the results show and write the findings.
